Structure of a finite non-commutative algebra set by a sparse multiplication table

Dmitriy Moldovyan, Alexandr Moldovyan, Nikolay Moldovyan

Abstract. Four-dimensional finite non-commutative associative algebras represent practical interest as algebraic support of post-quantum digital signature algorithms, especially algebras with two sided global unit, set by sparse basis vectors multiplication tables. A new algebra of the latter type, set over the field $GF(p)$, is proposed and its structure is investigated. The studied algebra is described as a set of $p^2 + p + 1$ commutative subalgebras of three different types. All subalgebras intersect strictly in the subset of scalar vectors. Formulas are derived for the number of subalgebras of each type.

1. Introduction

Development of practical post-quantum (PQ) public-key digital signature algorithms is one of current challenges in the area of cryptography, which attracts considerable attention from the research community [8, 9]. Among computationally difficult problems used as a basic primitive of PQ signature algorithms, the hidden discrete logarithm problem (HDLP) is of interest for the development of PQ signature schemes having high performance and comparatively small size of the public key and signature [1, 3, 5]. Usually the HDLP is set in finite non-commutative associative algebras (FNAAs).

Recently [2], FNAAs defined with a sparse basis vector multiplication table (BVMT) have been proposed to get higher performance of the HDLP-based signature algorithms. The structure of the FNAAs used as algebraic support play significant role in the design of PQ HDLP-based signature schemes [1, 6].

The present paper introduces a new 4-dimensional FNAA set by a sparse BVMT over the ground field $GF(p)$, where $p$ is an odd prime, and examines its structure from the point of view of decomposition into commutative subalgebras denoted as $\Psi$.

Keywords: non-commutative algebra, finite associative algebra, single-sided units, post-quantum cryptography, public-key cryptoscheme, signature scheme, discrete logarithm problem, hidden logarithm problem
2. Introduced 4-dimensional algebra

Suppose a finite 4-dimensional vector space is defined over the ground finite field $GF(p)$, where $p \geq 3$. Then defining additionally the vector multiplication that is distributive at the right and at the left relatively the addition operation one gets a finite 4-dimensional algebra. An algebra element $A$ can be denoted in the following two forms: $A = (a_0, a_1, a_2, a_3)$ and $A = \sum_{i=0}^{3} a_i e_i$, where $a_0, a_1, a_2, a_3 \in GF(p)$ are called coordinates; $e_0, e_1, e_2, e_3$ are basis vectors.

The vector multiplication operation of two 4-dimensional vectors $A$ and $B$ is defined as $AB = \sum_{i=0}^{3} \sum_{j=0}^{3} a_i b_j (e_i e_j)$, where every of the products $e_i e_j$ is to be replaced by a single-component vector $\lambda e_k$, where $\lambda \in GF(p)$, indicated in the cell at the intersection of the $i$th row and $j$th column of so called BVMT, like the proposed sparse Table 1. To define associative vector multiplication operation the BVMT should define associative multiplication of all possible triples of the basis vectors $(e_i, e_j, e_k) : (e_i \circ e_j) \circ e_k = e_i \circ (e_j \circ e_k)$.

Table 1 with the structural constant $\lambda \neq 0$ defines the associative vector multiplication operation. Solving the vector equations $AX = X$ and $XA = A$, where $X = (x_0, x_1, x_2, x_3)$ is the unknown, one can easily prove that the 4-dimensional FNAA set by Table 1 contains global two-sided unit $E = (0, 0, 1, 1)$.

Consider the vector equation $AX = A$ that is reduced to the following system of four linear equations in $GF(p)$:

$$\begin{cases}
  a_3 x_0 + a_0 x_2 = 0; \\
  a_0 x_3 + a_2 x_1 = 0; \\
  \lambda a_1 x_0 + a_2 x_2 = 1; \\
  \lambda a_0 x_1 + a_3 x_3 = 1.
\end{cases}$$

(1)

If the system (1) has solution, then the vector $A$ is invertible. It is easy to derive the following invertibility (non-invertibility) condition:

$$\lambda a_0 a_1 \neq a_2 a_3 \quad (\lambda a_0 a_1 = a_2 a_3).$$

(2)

The condition (2) defines (see, for example, [1]) the following value of the order $\Omega$ of the algebra multiplicative group (the number of invertible vectors contained in the algebra):

$$\Omega = p(p-1)(p^2-1).$$

(3)

3. Structure of the algebra

To study the structure of the FNAA set by Table 1, we apply the method used earlier in [1]. Consider the set of the vectors $X$ that are permutable with a fixed vector $A = (a_0, a_1, a_2, a_3)$. The vectors $X = (x_0, x_1, x_2, x_3)$ can be computed as solutions of the vector equation $A \circ X = X \circ A$. Evidently, if $X$ and $X'$ are
solutions, then $X \pm X'$ and $XX'$ are also solutions. Therefore the set of solutions $(\Psi_A)$ is a subalgebra. The said vector equation can be reduced to the following system of three linear equations with the unknowns $x_0, x_1, x_2,$ and $x_3$:

\[
\begin{cases}
(a_3 - a_2)x_0 + a_0x_2 - a_0x_3 = 0; \\
(a_2 - a_3)x_1 - a_1x_2 + a_1x_3 = 0; \\
ax_0 - ax_1 = 0.
\end{cases}
\tag{4}
\]

Depending on the values $a_0, a_1, a_2,$ and $a_3,$ the following cases should be considered.

I. $a_0 = a_1 = 0.$ The system (4) reduces to

\[
\begin{cases}
(a_3 - a_2)x_0 = 0; \\
(a_2 - a_3)x_1 = 0.
\end{cases}
\]

If $a_2 \neq a_3,$ then $x_0 = x_1 = 0$ one gets the solution space

\[X = (x_0, x_1, x_2, x_3) = (0, 0, i, j),\]

where $i, j = 0, 1, \ldots p - 1.$ The set (5) describes a subalgebra $\Psi_A$ of order $p^2,$ which contains $2p - 1$ different non-invertible vectors of the forms $(0, 0, i, 0)$ and $(0, 0, 0, j).$ Multiplicative group $\Gamma_1$ of this subalgebra has order $\Omega_1 = p^2 - (2p - 1) = (p - 1)^2.$ One can show that the group $\Gamma_1$ possesses 2-dimensional cyclicity (in terms of [7]), i.e., its minimum generator system includes two vectors of the order $p - 1.$

If $a_3 = a_2,$ (the algebra element $A$ is a scalar vector), then the solution space of the system (4) includes all vectors of the algebra.

II. $a_0 \neq 0; a_1 = 0.$ We have The system (4) can be reduced to

\[
\begin{cases}
x_3 = x_2 + \frac{a_3 - a_2}{a_0}x_0; \\
x_1 = 0
\end{cases}
\]

and the solution space of the system (4) is described as follows:

\[X = (x_0, x_1, x_2, x_3) = \left(i, 0, j, j + \frac{a_3 - a_2}{a_0}i\right),\]

The BVMT setting the studied 4-dimensional FNAA; $\lambda \neq 0.$

where \(i, j = 0, 1, \ldots p - 1\). The latter set includes non-invertible vectors satisfying the condition \(j \left(j + \frac{a_3 - a_2}{a_0}i\right) = 0\). The latter condition sets the following two subsets of non-invertible vectors: i) \(X = \left(i, 0, 0, \frac{a_3 - a_2}{a_0}i\right)\) and ii) \(X = \left(i, 0, -\frac{a_3 - a_2}{a_0}i, 0\right)\), which intersect in the zero vector \((0, 0, 0, 0)\).

II.a) \(a_2 \neq a_3\). This subcase corresponds to subalgebra \(\Psi_A\) of order \(p^2\) which includes \(2p - 1\) non-invertible vectors and multiplicative group \(\Gamma_1\) of order \(\Omega_1 = (p - 1)^2\).

II.b) \(a_2 = a_3\). This subcase corresponds to a subalgebra \(\Psi_A\) of order \(p^2\), which includes \(p\) non-invertible vectors of the form \((i, 0, 0, 0)\) and contains a multiplicative group \(\Gamma_2\) of order \(\Omega_2 = p^2 - p = p(p - 1)\). It is easy to prove that the group \(\Gamma_2\) is cyclic.

III. \(a_0 = 0; a_1 \neq 0\). The system (4) reduces to:

\[
\begin{align*}
x_3 &= x_2 + \frac{a_3 - a_2}{a_1}x_1; \\
x_0 &= 0
\end{align*}
\]

and the solution space of the system (4) is described as follows:

\[
X = (x_0, x_1, x_2, x_3) = \left(0, i, j + \frac{a_3 - a_2}{a_1}i\right),
\]

where \(i, j = 0, 1, \ldots p - 1\). The set (7) includes non-invertible vectors satisfying the condition \(j \left(j + \frac{a_3 - a_2}{a_0}i\right) = 0\) which sets the following two subsets of non-invertible vectors: i) \(X = \left(0, i, 0, \frac{a_3 - a_2}{a_0}i\right)\) and ii) \(X = \left(0, i, -\frac{a_3 - a_2}{a_0}i, 0\right)\).

III.a) \(a_2 \neq a_3\). This subcase corresponds to a subalgebra \(\Psi_A\) of order \(p^2\) which includes \(2p - 1\) non-invertible vectors and multiplicative group \(\Gamma_1\) of order \(\Omega_1 = (p - 1)^2\).

III.b) \(a_2 = a_3\). This subcase corresponds to a subalgebra \(\Psi_A\) of order \(p^2\), which includes \(p\) non-invertible vectors of the form \((0, i, 0, 0)\) and contains a cyclic multiplicative group of the \(\Gamma_2\) type and of order \(\Omega_2 = p(p - 1)\).

IV. \(a_0 \neq 0; a_1 \neq 0\). One can write \(x_1 = x_0a_1a_0^{-1}\). At the latter condition the first and the second equations in (4) have the same solutions, therefore, the system (4) reduces to

\[
\begin{align*}
(a_3 - a_2)x_0 + a_0x_2 - a_0x_3 &= 0; \\
x_1 &= \frac{a_1}{a_0}x_0
\end{align*}
\]

and the solution space of the system (4) is described as follows:

\[
X = (x_0, x_1, x_2, x_3) = \left(i, \frac{a_1}{a_0}i, j, j + \frac{a_3 - a_2}{a_0}i\right),
\]
where \( i, j = 0, 1, \ldots, p - 1 \). Taking into account the non-invertibility condition in (2), for non-invertible vectors from the set (8) one can write

\[
\lambda \frac{a_1}{a_0} i^2 = j^2 + \frac{a_3 - a_2}{a_0} ji;
\]

\[
i^2 - \frac{a_3 - a_2}{\lambda a_1} ji - \frac{a_0}{\lambda a_1} j^2 = 0; \quad (9)
\]

Fixing the value of \( j \), one gets the following solutions of the latter quadratic equation

\[
i = \frac{a_3 - a_2 \pm \sqrt{\Delta}}{2 \lambda a_1} j, \quad \text{where} \quad \Delta = (a_3 - a_2)^2 + 4 \lambda a_0 a_1. \quad (10)
\]

IV,a) \( \Delta \neq 0 \) is a quadratic residue in \( GF(p) \). The number of non-invertible vectors in the set (8) equals to \( 2^p - 1 \) and the multiplicative group of the subalgebra \( \Psi_A \) represented by the set (8) is attributed to the \( \Gamma_1 \) type.

IV,b) \( \Delta \neq 0 \) is a quadratic non-residue in \( GF(p) \). The set (8) includes the single non-invertible vector \((0, 0, 0, 0)\) and represents a finite field that is isomorphic to the \( GF(p^2) \) field. The multiplicative group \( \Gamma_3 \) of this subalgebra is cyclic and has order equal to \( \Omega_3 = p^2 - 1 \).

IV,c) \( \Delta = 0 \). The number of non-invertible vectors in the set (8) equals to \( p \) and the set (8) is a \( \Psi_A \) subalgebra that includes multiplicative group of the \( \Gamma_2 \) type and of order \( \Omega_2 = p(p - 1) \).

Note that for a non-invertible vector \( A \) we have \( \lambda a_0 a_1 = a_2 a_3 \). Therefore, in the latter case \( \Delta = (a_3 + a_2)^2 \) and, if \( a_3 \neq -a_2 \), the set (8) contains \( 2p - 1 \) non-invertible vectors (including \( A \)) and represents an algebra with multiplicative group of the \( \Gamma_1 \) type, which possesses 2-dimensional cyclicity and has order equal to \( (p - 1)^2 \). If \( a_3 = -a_2 \), then the multiplicative group of the \( \Psi_A \) subalgebra is attributed to the \( \Gamma_2 \) type.

Thus, every algebra element \( A \) that is not a scalar vector defines a subalgebra \( \Psi_A \) of order \( p^2 \). Suppose the set of scalar vectors is denoted as \( \Sigma \). Evidently, \( \Sigma \) is contained in every subalgebra \( \Psi_A \). The next Proposition 1 shows that every subalgebra \( \Psi_A \) defined by a vetor \( A \notin \Sigma \) is commutative.

**Proposition 1.** Suppose \( A \notin \Sigma \), \( X, X' \in \Psi_A \). Then \( XX' = X'X \).

**Proof.** Consecutively, fix every of the sets (5), (6), (7), and (8). For every of the latter four cases, select arbitrary two elements \( X \) and \( X' \) contained in the fixed set and, using Table 1, compute the vectors \( V_1 = XX' \) and \( V_2 = X'X \). For every of the cases one gets \( V_1 = V_2 \). \( \square \)

**Proposition 2.** Suppose \( A \notin \Sigma \), \( X \in \Psi_A \), and \( X \notin \Sigma \). Then \( \Psi_X \) coincide with \( \Psi_A \).

**Proof.** Suppose \( X' \in \Psi_A \). Since \( X \in \Psi_A \), due to Proposition 1, we have \( XX' = X'X \), i. e., \( X' \in \Psi_X \). Respectively, if \( X' \in \Psi_X \), then, taking into account that \( A \in \Psi_X \) and Proposition 1, we have \( AX' = X'A \), i. e., \( X' \in \Psi_A \). \( \square \)
Due to Proposition 2, one can see that every non-scalar vector $X$ is contained in a unique $\Psi$ subalgebra, namely, in subalgebra $\Psi_X$.

One has the following three types of the commutative $\Psi$ subalgebras: $\Psi_1$, $\Psi_2$, and $\Psi_3$, characterized in structure of their multiplicative group, namely, multiplicative group of a $\Psi_h$ subalgebra represents a group of the $\Gamma_h$ type, where $h = 1, 2, 3$.

4. Number of the $\Psi_1$, $\Psi_2$, and $\Psi_3$ subalgebras

The studied 4-dimensional FNAA has order $p^4$ and contains exactly three types of commutative subalgebras of order $p^2$. Due to Proposition 2, one can see that arbitrary two of the said subalgebras intersect exactly in the set of scalar vectors and every non-scalar vector is included in a unique $\Psi$ subalgebra. Every $\Psi$ subalgebra contains $p^2 - p$ unique non-scalar vectors. The studied FNAA contains $p^2 - p$ unique non-scalar vectors, therefore for the number $\eta$ of the $\Psi$ subalgebras one gets the following formula:

$$\eta = \frac{p^4 - p}{p^2 - p} = p^2 + p + 1.$$  \hfill (11)

Suppose $k$, $t$, and $u$ denote numbers of different subalgebras of the $\Psi_1$, $\Psi_2$, and $\Psi_3$ types, correspondingly. Then we have $\eta = k + t + u$,

$$k + t + u = p^2 + p + 1.$$  \hfill (12)

Consider the multiplicative groups of the types $\Gamma_1$, $\Gamma_2$, and $\Gamma_3$. The values $k$, $t$, and $u$ are equal to the numbers of different $\Gamma_1$, $\Gamma_2$, and $\Gamma_3$ groups, correspondingly. Taking into account that the set $\Sigma$ includes $p - 1$ invertible vectors and the orders of the $\Gamma_1$, $\Gamma_2$, and $\Gamma_3$ groups are equal to $(p - 1)^2$, $p(p - 1)$, and $(p^2 - 1)$, one can write

$$(\Omega_1 - (p - 1))k + (\Omega_2 - (p - 1))t + (\Omega_3 - (p - 1))u = \Omega - (p - 1);$$

$$(p - 1)^2 - (p - 1))k + (p(p - 1) - (p - 1))t + (p^2 - 1 - (p - 1))u =$$

$$= p(p - 1)(p^2 - 1) - (p - 1);$$

$$(p - 2)k + (p - 1)t + pu = p^3 - p - 1.$$  \hfill (13)

Every fixed $\Psi_2$ subalgebra contains $p - 1$ unique nonzero non-invertible vectors $N$ such that $\Psi_N = \Psi_2$. To find the value $t$, consider the number of non-invertible vectors $A$ relating to the Case IV,c), i. e. $a_0 \neq 0$; $a_1 \neq 0$; $\Delta = 0$, which define the commutative subalgebras containing multiplicative groups of the $\Gamma_2$ type. Such vectors satisfy the conditions $a_2a_3 = \lambda a_0a_1 \neq 0$ and $\Delta = (a_3 + a_2)^2 = 0$. From the latter condition we have $a_3 = -a_2$. Thus, the Case IV,c) gives $(p - 1)^2$ different vectors $A = (i, -j^2 \lambda^{-1} i^{-1}, j, -j)$, where $i, j = 1, 2, \ldots, p - 1$, which define the subalgebras $\Psi_A$ of the $\Psi_2$ type. Each of the subcases $\Pi,b)$ and $\PiII,b)$ gives other
Structure of a 4-dimensional finite non-commutative algebra

$p - 1$ unique vectors $A$ composing a unique subalgebra of the $\Psi_2$ type. Totally, we have $(p - 1)^2 + 2(p - 1) = (p - 1)(p + 1)$ unique non-invertible vectors defining all subalgebras of the $\Psi_2$ type. Every subalgebra of the $\Psi_2$ type contains $p - 1$ of the said non-invertible vectors and $t$ algebras contain all vectors $A$: $t(p - 1) = (p - 1)(p + 1)$, therefore,

$$t = p + 1.$$  \hspace{1cm} (14)

From (12), (13), and (14) we have

$$k = \frac{p(p + 1)}{2}; \quad u = \frac{p(p - 1)}{2}.$$  \hspace{1cm} (15)

5. Discussion and conclusion

In several HDLP-based digital signature algorithms on FNAAs there are used hidden groups possessing 2-dimensional cyclicity [5, 6, 1] and issues about existence and number of such groups have critical significance. The results obtained on the study of the structure of the 4-dimensional FNAA defined by Table 1 show that this algebra contains a sufficiently large number of groups with two-dimensional cyclicity. Therefore, the said algebra can be used as an algebraic support of the mentioned digital signature algorithms. Previously [6, 1], a similar study was performed for the algebras specified in Tables 2 and 3. The results of this work
and of [6, 1] are mainly coincided, namely, the structure of algebras set by sparse
Tables 1, 2 and 3 is described from a single position. Each of these algebras is
divided into commutative subalgebras of order \( p^2 \), which are attributed exactly
to the following three types \( \Psi_1, \Psi_2, \) and \( \Psi_3 \). The number of the subalgebras
of every type is described by the formulas (14) and (15). One can expect that
other 4-dimensional FNAAs set by other sparse basis vector multiplication tables
also possesses the same structure, however, the finite quaternion-like algebras [4]
possess another structure.

Study of the structure of the FNAAs used as algebraic support of the HDLP-
based signature schemes appears to be an important stage of the development of
the said cryptoschemes.
